# Ground-Water Quality for Grainger County, Tennessee

By Jess D. Weaver, Anant R. Patel, and Andrew C. Hickey

## Abstract

The residents of Grainger County depend on ground water for many of their daily needs including personal consumption and crop irrigation. To address concerns associated with ground-water quality related to domestic use, the U.S. Geological Survey collected water samples from 35 wells throughout the county during the summer 1992. The water samples were analyzed to determine if pesticides, nutrients, bacteria, and other selected constituents were present in the ground water. Wells selected for the study were between 100 and 250 feet deep and yielded 10 to 50 gallons of water per minute. Laboratory analyses of the water found no organic pesticides at concentrations exceeding the primary maximum contaminant levels established by the State of Tennessee for wells used for public supply. However, fecal coliform bacteria were detected at concentrations exceeding the State's maximum contaminant level in water from 15 of the 35 wells sampled. Analyses also showed several inorganic compounds were present in the water samples at concentrations exceeding the secondary maximum contaminant level.

## INTRODUCTION

In Tennessee, more than half of the population depends on ground water to meet its daily needs, including personal consumption (Hutson, 1991). Determination of the present ground-water quality in an area provides a basis to assess potential public health risks and suitability of the water for consumptive use and other use, such as crop irrigation. Water-quality determinations also provide data that can be used as benchmarks for determining trends in ground-water quality conditions.

About 75 percent of the residents of Grainger County, Tennessee, depend on private wells for their drinking-water supply (S.S. Hutson, U.S. Geological Survey, written commun., 1993). In addition, wells are an important source of irrigation supply for the vegetable producers of the county. To address concerns associated with ground-water quality in this area, the U.S. Geological Survey, in cooperation with Grainger County, collected and analyzed water samples from 35 wells during the summer 1992 (fig. 1). The main objective of this study was to determine if pesticides, nutrients, bacteria, and other selected constituents were present in the ground water at selected well locations throughout the county.

## **ACKNOWLEDGMENTS**

The authors gratefully acknowledge the contributions of Melinda Turner and Saundra Jarvis of the Clinch-Powell Resource Conservation and Development Council. Their efforts in recruiting volunteers for participation in the well-sampling program was instrumental in the successful completion of this project.

## **WELL SELECTION CRITERIA**

Initially, data for about 500 wells in Grainger County were retrieved from the Tennessee Department of Environment and Conservation, Division of Groundwater Protection, computer data base (Luke Ewing, Tennessee Department of Environment and Conservation, written commun., 1992). The number of well locations was reduced from about 500 to around 100 wells using the following criteria:

- (1) Only wells having a depth between 100 and 250 feet were selected.
  - (2) Only wells having a yield between 10 and 50 gallons of water per minute were selected.
- The owners of these estimated 100 wells were asked by representatives of the Clinch-Powell Resource Conservation and Development Council to participate in the study. This process resulted in the selection of 35 wells for sampling at locations distributed throughout the county (table 1). The selected wells are used for domestic supply.

## **SAMPLE COLLECTION**

Water samples from each well were collected after pumping the well until temperature and specific-conductance readings had stabilized. Typically, this process required 20 to 30 minutes of continuous pumping before water samples were collected. The water was withdrawn using the pump already in each well, and the samples were collected at a point prior to the water reaching any residential water-treatment system. Two wells were sampled twice for selected constituents because the original water samples were destroyed during shipment to the laboratory. Equipment malfunctions and high concentrations of particulate matter prevented the measurement of pH and alkalinity in water from a few wells.

## **RESULTS**

The results of the water-quality analyses were compared to the regulations for drinking-water quality established by the Tennessee Department of Health and Environment (1993). These regulations apply to water provided by public water-supply systems and thus are not enforceable for domestic water-supply systems, but the regulations provide a basis for evaluating potential public health risks and assessing the suitability of the water for consumptive use. Primary maximum contaminant levels have been set by the State for the constituents or properties that can adversely affect human health. Secondary maximum contaminant levels have been set by the State for the constituents or properties that only affect the taste, odor, or appearance of the water.

Concentrations of iron (six wells) and manganese (seven wells) exceeded the secondary maximum contaminant level of 300 micrograms per liter and 50 micrograms per liter, respectively (table 2).

Total copper concentrations were greater than the detection limit in six wells (table 2). Nitrite ( $\text{NO}_2$ ) and nitrate ( $\text{NO}_3$ ) concentrations were less than the primary maximum contaminant levels in all of the wells sampled (table 3).

No organic pesticides were present at concentrations greater than primary maximum contaminant levels in any of the 35 wells that were sampled (table 3). Additionally, the occurrences of organic pesticide concentrations above the detection limit of the laboratory were limited to trace amounts of atrazine found at wells 2, 8, and 10, and aldicarb at well 5 (table 3).

Fecal coliform bacteria were detected at concentrations exceeding maximum contaminant levels of 0 colonies per 100 milliliters in water samples from 15 of the 35 wells (table 4). Concentrations listed as less than 1 indicate no bacterial colony content was observed in that particular water sample. In the 15 water samples having detectable fecal coliform, concentrations ranged from 2 to 3,400 colonies per 100 milliliters. The occurrence of bacteria in water samples was scattered throughout the county with no apparent clustering of high concentrations in any specific area.

Additional results from the sampling program indicated the pH of water from well 28 was not within the acceptable range for secondary regulations. Dissolved solids in water from well 26 also exceeded the secondary regulation concentration. Methylene blue, a compound found in many household soaps and detergents, was detected in trace amounts in 23 wells. However, concentrations of methylene blue were less than the secondary maximum contaminant level in all of the sampled wells.

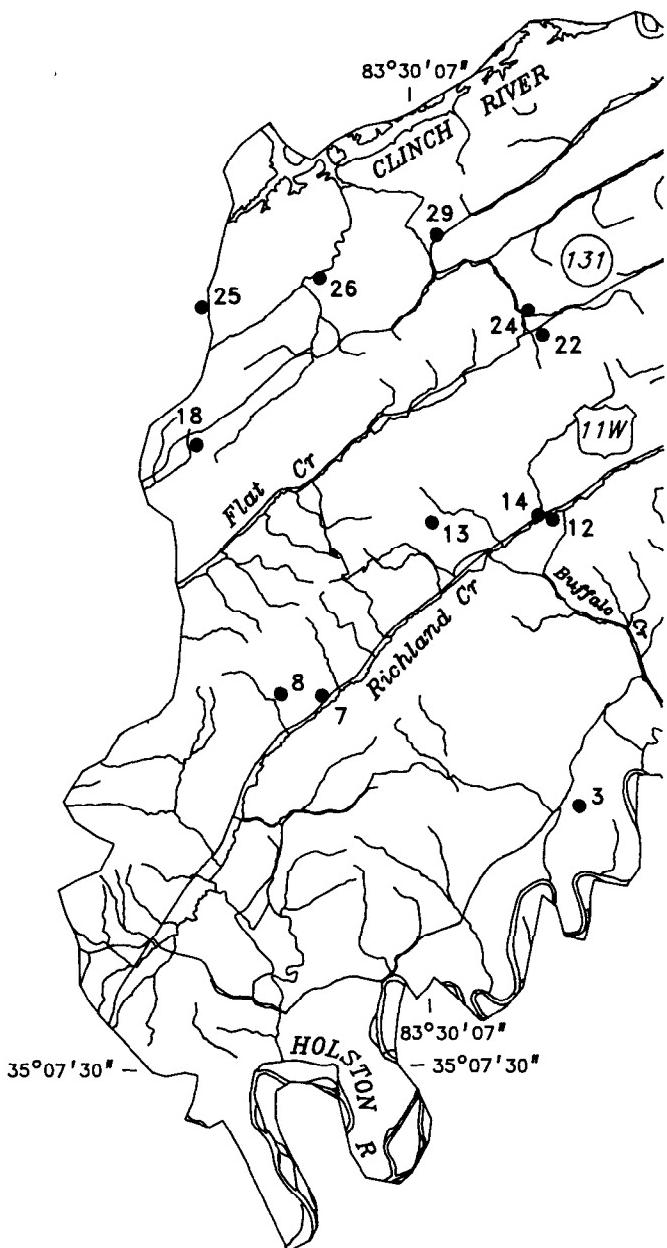

Cation-anion analyses revealed that the most common water type in the county was calcium bicarbonate. However, two exceptions to this general trend were observed:

- (1) Water collected from wells located in the middle-southern part of the county was predominantly of the calcium-magnesium bicarbonate type.
- (2) Water collected from wells 23 and 34 was dominated by the sodium ion and was classified as sodium bicarbonate.

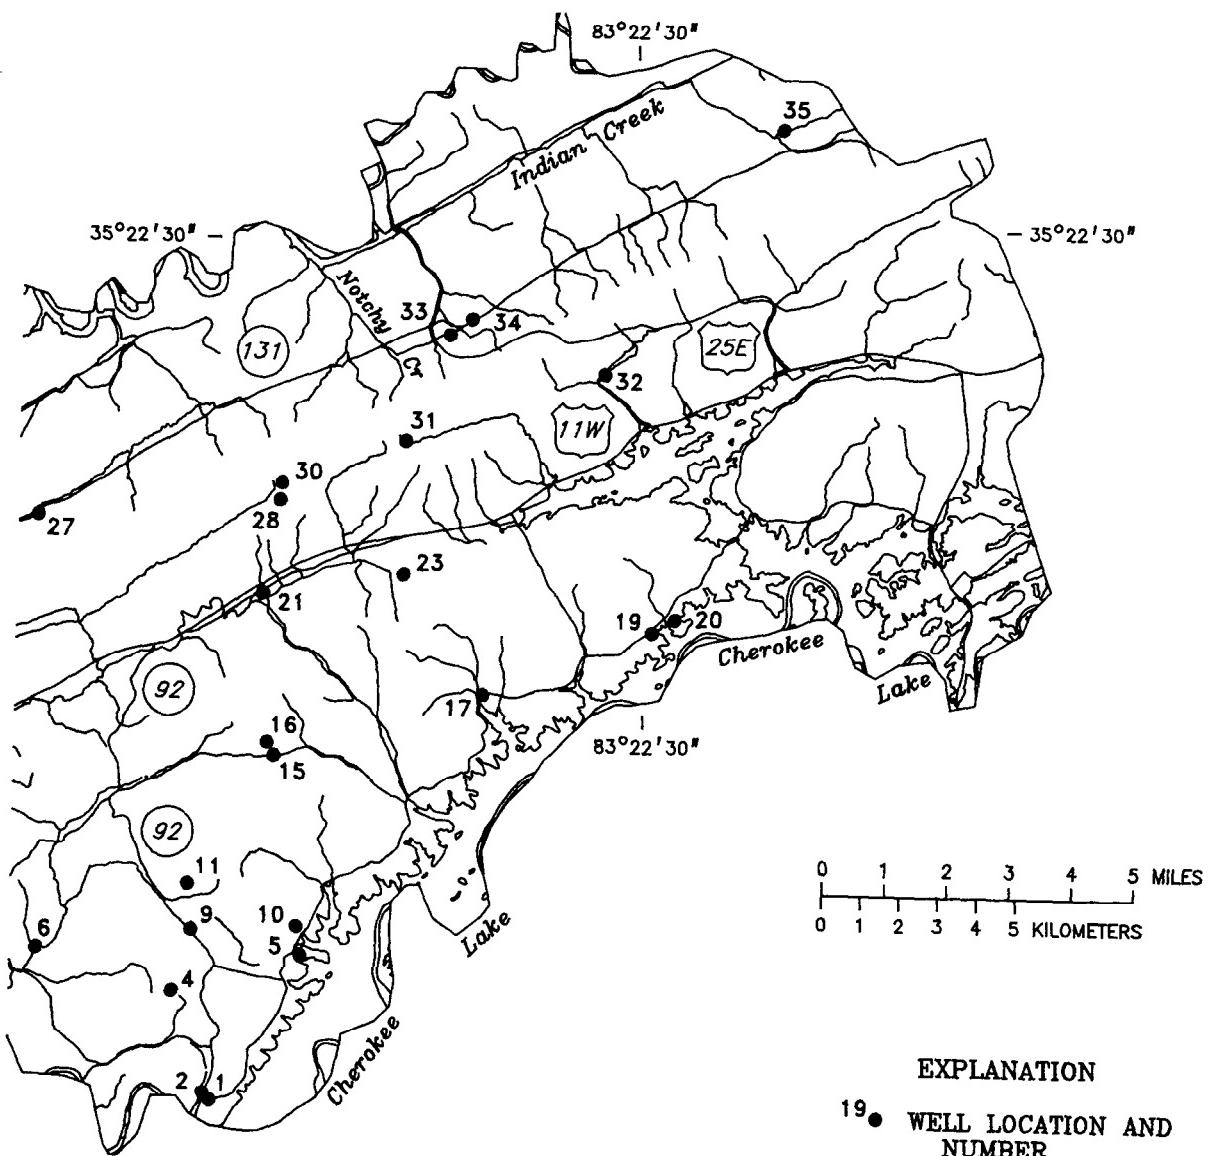

The concentrations of cations and anions for well 28 were determined to be in error during data verification after the sampling program was completed. This determination was based on a cation-anion ratio percent difference of 48.9 percent. A second laboratory analysis of the sample revealed little improvement in the cation-anion ratio, therefore, the results were deleted from table 2.
